ABSTRACT

A 62-year-old woman with a history of genetically confirmed hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) was admitted because of chronic diarrhoea. During admission she developed a rapidly progressive nephrotic syndrome. Reactive amyloid A (AA) amyloidosis was confirmed after colonic and renal biopsy which showed deposition of amyloid. After initial treatment with high-dosed corticosteroids, therapy was switched to anakinra, an IL-1 receptor antagonist, but her symptoms persisted. After cessation of anakinra, a marked exacerbation of the intestinal symptoms was noted. Nine months after the initial diagnosis of reactive amyloidosis without any amelioration of the symptoms and a decreasing quality of life, our patient declined further treatment and died soon after. This case demonstrates that AA amyloidosis does occur in patients with HIDS and can present with intestinal symptoms and proteinuria. Once amyloidosis is diagnosed the goal of treatment is to prevent further complications. In this case report we give an overview of previous cases with amyloidosis complicating HIDS with the treatments received and propose a step-up treatment plan for future cases.

KEYWORDS

AA amyloidosis, hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS), mevalonate kinase deficiency (MKD), anakinra; IL-1 blockage.

What was known on this topic?

AA amyloidosis is a known complication in periodic fever syndromes but rare in HIDS. If left untreated it can lead to intestinal disease and/or progressive cardiac and renal failure.

What does this add?

In this article we present the seventh patient with AA amyloidosis secondary to HIDS, describe treatment and outcome of treatment with anakinra, give an overview of literature on treatments used previously and propose a step-up treatment plan for future cases.

INTRODUCTION

Hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS), a hereditary periodic fever syndrome, is an autosomal-recessive, auto-inflammatory disorder mediated by mevalonate kinase deficiency. The main symptoms are recurrent febrile attacks, arthralgia, cervical lymphadenopathy, diarrhoea and rash. Diagnosis is confirmed by genetic analysis since multiple mutations have been described in the mevalonate kinase (MVK) gene. Little is known about the mechanism leading to an auto-inflammatory condition as a result of reduced MVK activity. Ex-vivo experiments suggest that peripheral blood mononuclear cells produce large amounts of IL-1, hypothetically as a result of either excess or lack of isoprenoid products. Recently, it was hypothesised that a lack of 25-hydroxycholesterol, a metabolite in the cholesterol pathway, plays a role in the pathogenesis. AA amyloidosis is a known complication of hereditary periodic fever syndromes, especially familial Mediterranean fever in which the incidence has been reported to be as high as 60-75%. Reactive amyloidosis secondary to HIDS is relatively rare. Only six cases of amyloidosis secondary to HIDS have been reported in the literature. Literature on the treatment of patients with
AA amyloidosis secondary to hereditary periodic fever syndromes other than familial Mediterranean fever is very sparse.

We present the seventh case of a patient with reactive AA amyloidosis secondary to HIDS and evaluate the response to IL-1 blockage in the progression of amyloidosis.

**CASE REPORT**

We present a 62-year-old female patient with genetically confirmed HIDS. She was heterozygote for the I268T and V377I mutations of the MKV gene. The patient was admitted with chronic diarrhoea. During admission she developed a rapidly progressive nephrotic syndrome. Physical examination revealed marked oedema up to the patient’s waist. Laboratory results showed: serum creatinine levels up to 194 µmol/l corresponding to an estimated glomerular filtration rate of 23 ml/min/1.73 m², blood urea nitrogen 10 mmol/l, phosphate 1.73 mmol/l, albumin 20 g/l and cholesterol 6.8 mmol/l. The highest concentration of serum amyloid A was 15 mg/l (reference value 0-4 mg/l). Mevalonic acid in the urine had a concentration of 3 µmol/mmol (reference value < 1 µmol/mmol).

Colon and renal histological biopsies showed deposition of amyloid, present in small arteries and in the kidney, also in glomeruli. Positive Congo-red staining is shown in figure 1. Immunohistochemical staining for AA amyloid (antibody clone MC1, Dako bv, Belgium) was positive (figure 1).

Echocardiography, performed to assess cardiac involvement, revealed concentric hypertrophy with an echographic aspect of cardiac amyloidosis. On the computed tomography scan of the abdomen the walls of the terminal ileum and sigmoid showed signal enhancement and wall thickening.

Initial treatment with high-dosed corticosteroids showed no improvement in the patient’s intestinal symptoms or proteinuria, hence treatment with anakinra, an IL-1 receptor antagonist (100 mg/day subcutaneously) was initiated. Several months after initiation of therapy with anakinra, the proteinuria persisted and no improvement in renal function was observed; for this reason the line of treatment was discontinued. However, after cessation of IL-1 blockage, a marked exacerbation of the intestinal symptoms was noted. Gastric biopsy revealed amyloid depositions in the gastric microvasculature. Nine months after the initial diagnosis of reactive amyloidosis without any amelioration of the symptoms and a decreasing quality of life our patient declined further treatment and died soon after.

**DISCUSSION**

We present the seventh case of AA amyloidosis complicating HIDS. Amyloidosis is often suspected in hereditary periodic fever syndromes in particular familial Mediterranean fever, cryopyrin-associated periodic syndromes (CAPS; e.g. Muckle-Wells syndrome) and tumour necrosis factor receptor-associated periodic syndrome (TRAPS). However, in HIDS this major complication is rarely seen despite the favourable conditions for amyloidogenesis. The defect in mevalonate kinase, which leads to a deficiency of isoprenoid products, seems to have a protective effect on the development of amyloidosis. Farnesylated proteins seem to play an
important role here.18 Early diagnosis is crucial because limiting the progression of amyloidosis by treating the underlying disease is the cornerstone of the management strategy. No directed therapy for HIDS is currently available. Recently a comprehensive review of the treatments of hereditary periodic fever syndromes was published by Ter Haar et al.19 Specific data on the treatment of HIDS in this review suggest that colchicine is not effective.19-22 Statins were a promising therapy due their blocking effect in the isoprenoid pathway but results were also poor.19-22 NSAIDs and corticosteroids are commonly prescribed in clinical practice and are anecdotally reported to have positive results in HIDS.14,23 Therapy with anakinra, an IL-1 inhibitor and etanercept, a TNF-α inhibitor, has shown overall positive results.19-22 Recent publications with canakinumab, an IL-1 antibody, have also shown promising results.19-22 The question remains what the therapy of amyloidosis secondary to HIDS should be. In table 1 we summarise the results from previous case reports and small case series in the literature. Colchicine was found to be ineffective in one patient.6 Two reports of treatment with anakinra were published, the clinical course was not described in one of the reports and no clear benefit was seen in the other.6,20 Etanercept was reported to have good results in three patients.6,7,9 In the absence of a clear evidence-based treatment strategy we propose following a step-up plan for future cases. Stopping amyloidogenesis must be achieved by blocking the acute-phase response. Guidelines recommend initiating steroids but experts doubt their effectiveness.22 If the amyloidosis aggravates, the next step should be initiation of therapy is of major importance. The choice of a specific biological cannot be deducted from the literature and should be tailored to each patient based on individual characteristics. The key to limiting amyloid deposition and its target organ complications is early recognition and diagnosis.

DISCLOSURES

The authors declare no conflicts of interest. No funding or financial support was received.
